

Project 3 – Sales Analysis Dashboard Design

Premise

To use streamlit as the dashboard.

Reasons

streamlit creates a web page, which is user configurable which means a far more flexible layout than PowerBI or Tableau which have fixed design protocols.

HTML and CSS support further expands possibilities even though streamlit is not 100% CSS/HTML compatible.

Python compatibility making duplicating Jupyter notebook sections into the streamlit application very easy. With the other dashboard applications ETL steps need to be created from scratch in their methodology!

Design Ethos Concepts

- Use HTML concepts such as DIV to create unique sections in streamlit (streamlit containers)
- Use streamlit columns to segment contents of DIVs where necessary
- Use streamlit sidebar for main user options
- If I can do it widgets for interactive charts and application navigation such as sliders
- Use CSS to enhance the look and “feel” of the application

Project 3 – Sales Analysis Dashboard Design

Main Screen Design Concept

As we can see there is the sidebar on the left, then next to it one streamlit container.

Each radio button will create a container, to use as the page, then a sub container for the tabs. Each detail section is created as a container whose parent is the tab e.g. tab2 and plots etc use that container as their parent.

The only page without tabs is the overview page.

Each time a tab is selected a sub container is created inside the main one, then inside that columns are created if needed.

Each streamlit component is given a KEY value if it is to be manipulated in CSS.

Colour scheme will be determined via a “trial-and-error” methodology after testing, as at this time the colour theme for the project is undetermined. Also some consideration will be put into about the background colour of the plots, if it is feasible to change it then I will.

If possible will test with different screen resolutions.
